

Simulated Watershed Streamflow and Stream Temperature for Basins Draining to Long Island Sound

Preliminary Results from the Connecticut River and Long Island Sound Coastal Basins PRMS Watershed Model

David Bjerklie – USGS Connecticut Water Science Center

General: PRMS Model

- The model parameters were developed based on a general approach developed in a medium sized watershed in western Connecticut, and then extrapolated to the whole region.
- The PRMS model simulates the daily water balance for 511 HUC 12 watersheds in the NAWQA CONN study area and computes the quantity of runoff from groundwater sources, subsurface sources, and surface runoff sources as well as the runoff from snowmelt versus rainfall.

Precipitation Runoff Modeling System (PRMS) Model Structure

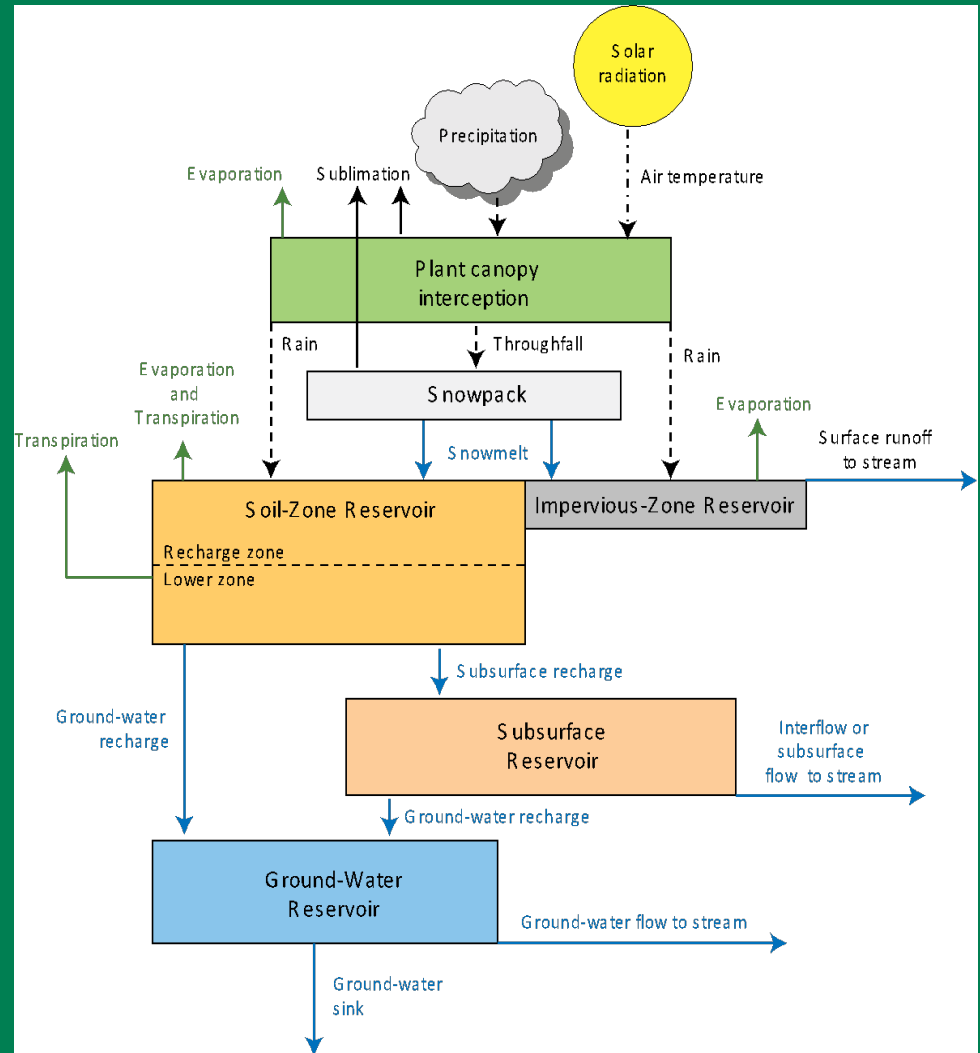

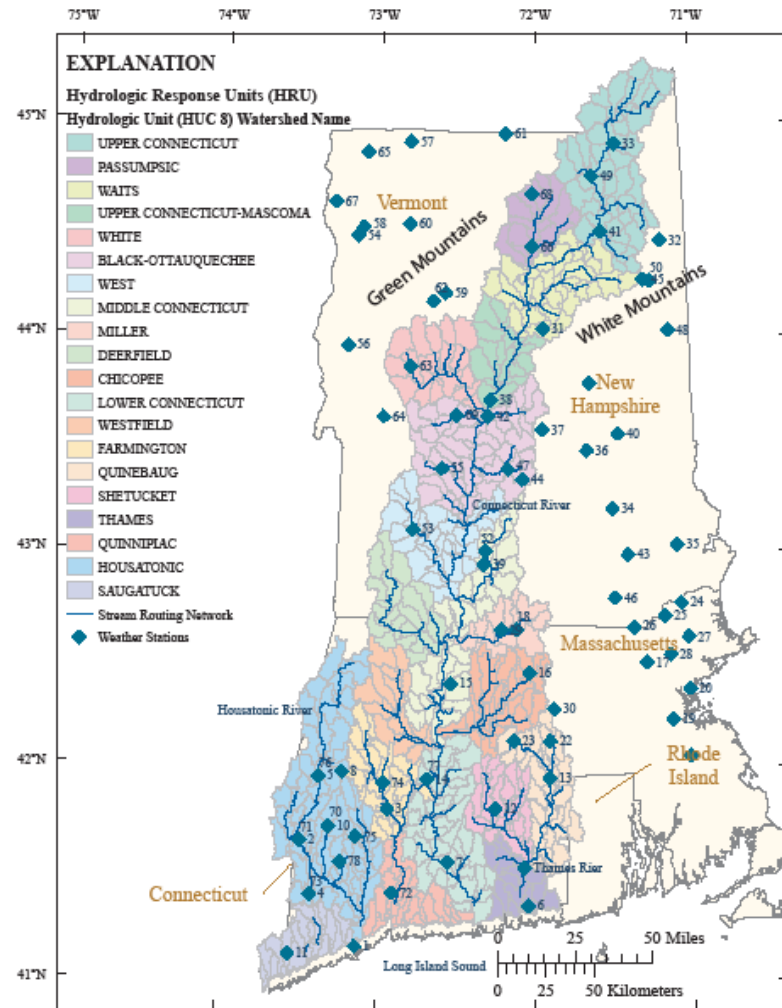

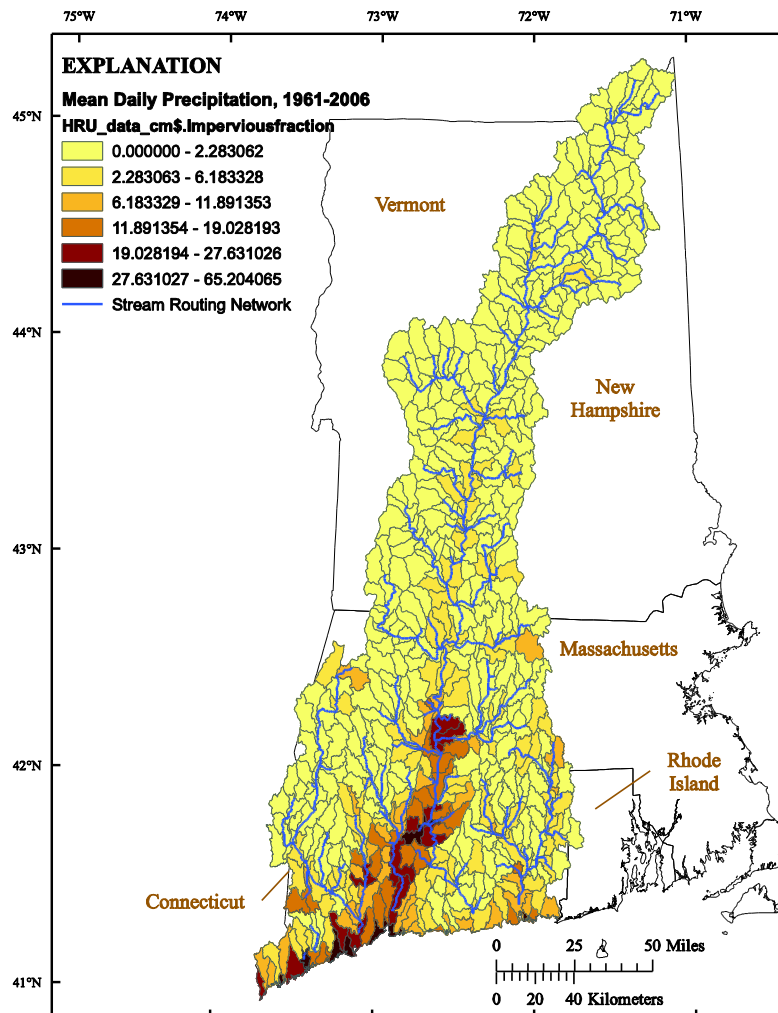

Diagram showing the hydrologic components as conceptualized in the Precipitation Runoff Modeling System (modified from Leavesley and others, 1983).

Study Area

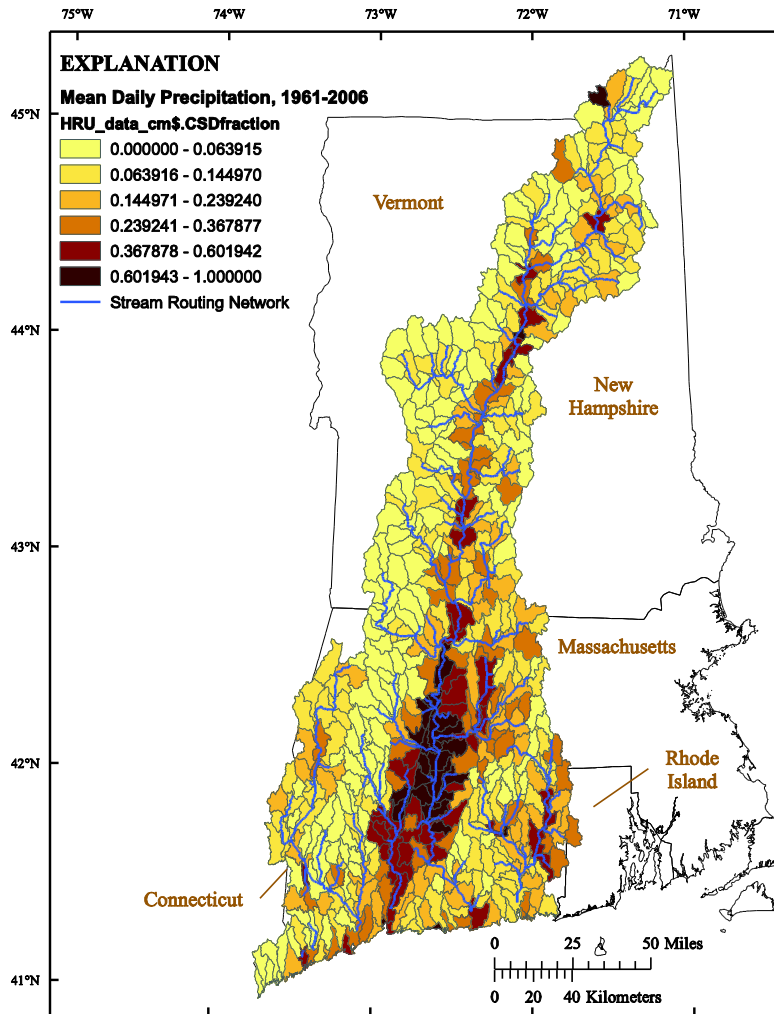

Study area showing major basins, hydrologic response units (511) and weather stations

average.

SNTemp

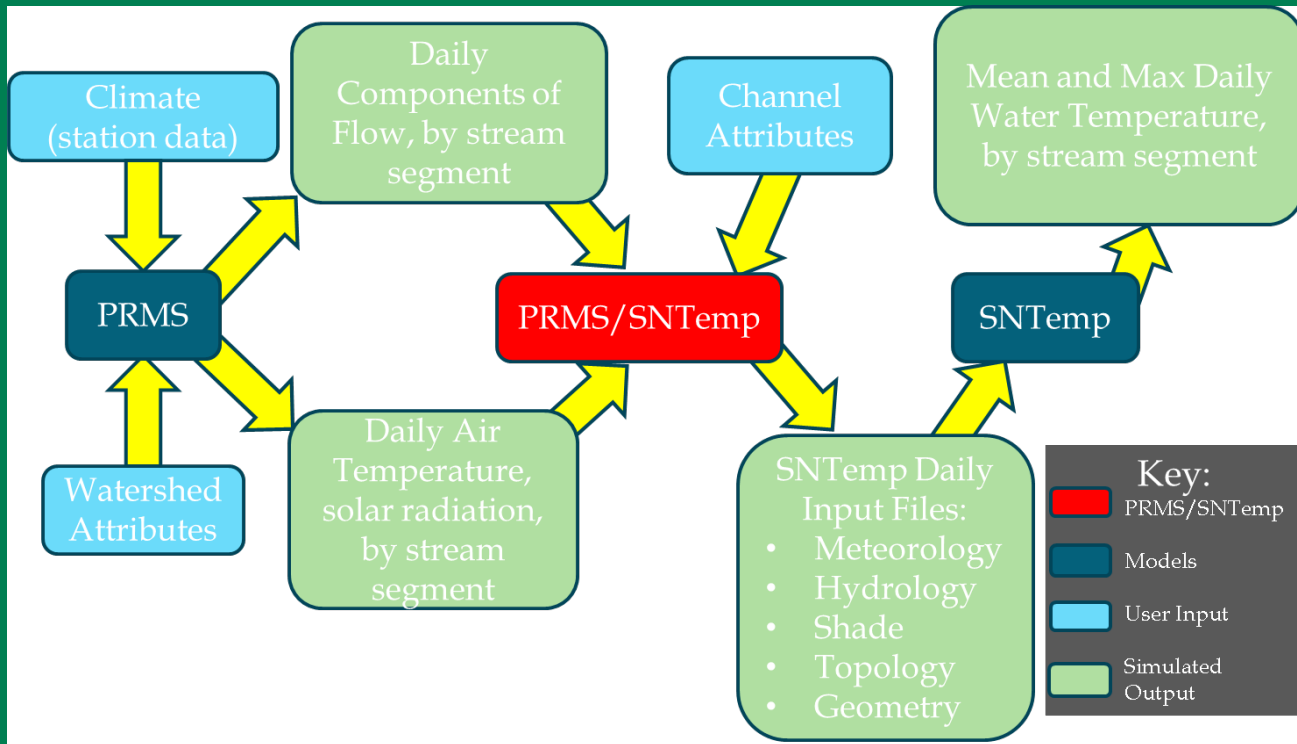

Diagram showing the information flow between the Precipitation Runoff Modeling System (PRMS), P2S, and the Stream Network Temperature Model.

PRMS Output Used in SNTEMP

- Streamflow
- Flow Components – Groundwater
Subsurface
Surface Runoff
- Air Temperature
- Solar Radiation

Simulated Average Daily Temperature

SNTemp simulated average daily stream temperature based on PRMS output.
